

**WP1:**  
**FAULTS AND TECTONICS**

*« Seismotectonic models: how better understanding tectonic processes and characterizing faults in intraplate domain?»*

*K. Manchuel (EDF) and L. Bollinger (CEA)*

First Symposium

November 28th, 2017

- Different alternatives in building seismotectonic models for PSHA studies:

Seismotectonic models	Inputs	
Zones	Geology, Geophysics, Tectonics, and seismicity	WP1
Faults	Geometry (surface and depth), kinematic, velocity, age of last movement	
Zoneless	Accurate seismicity catalogue that covers both historical and instrumental scales	WP2

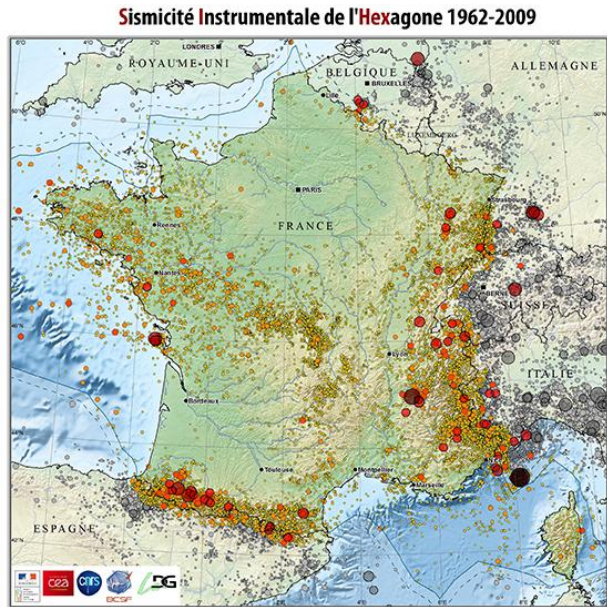

- Climatic processes tend, in intraplate regions characterized by low deformation rates, to erase potential tectonic markers → **large epistemic uncertainties associated with tectonics information introduced in SHA studies.**

→ WP1 objectives:

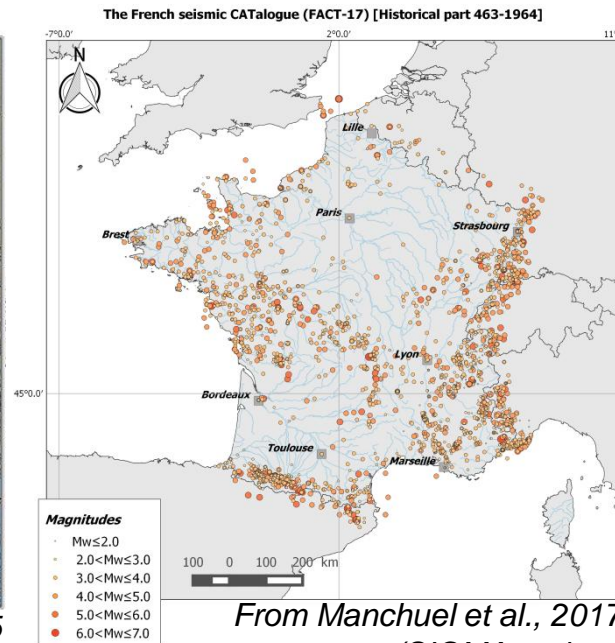

- Understanding the stress modulation on fault planes
- Improving knowledge of fault quaternary tectonic behaviour

in intraplate domains

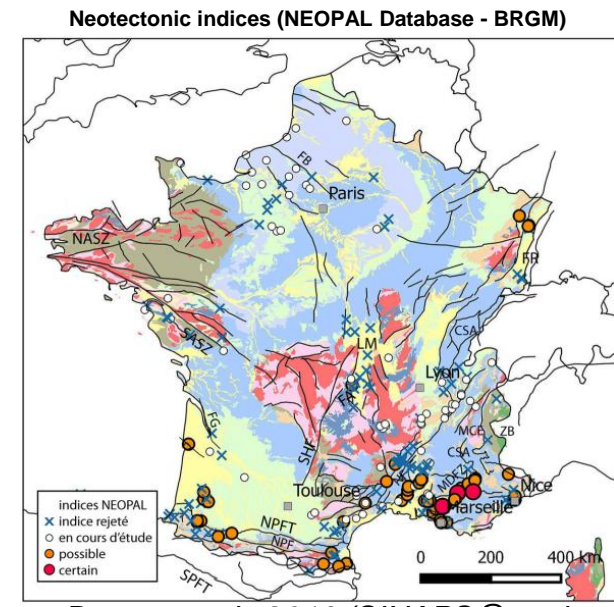

# Available data and questions (example of the French metropolitan territory)

Cara et al., 2015

From Manchuel et al., 2017  
(SIGMA project)

Bertran et al., 2016 (SINAPS@ project)

- Significant spatial variability of the seismicity, stable over instrumental and historical periods
- Representative of stress build up? Of stress release? Consistent with location of very long term seismicity?

# Available data and questions (example of the French metropolitan territory)

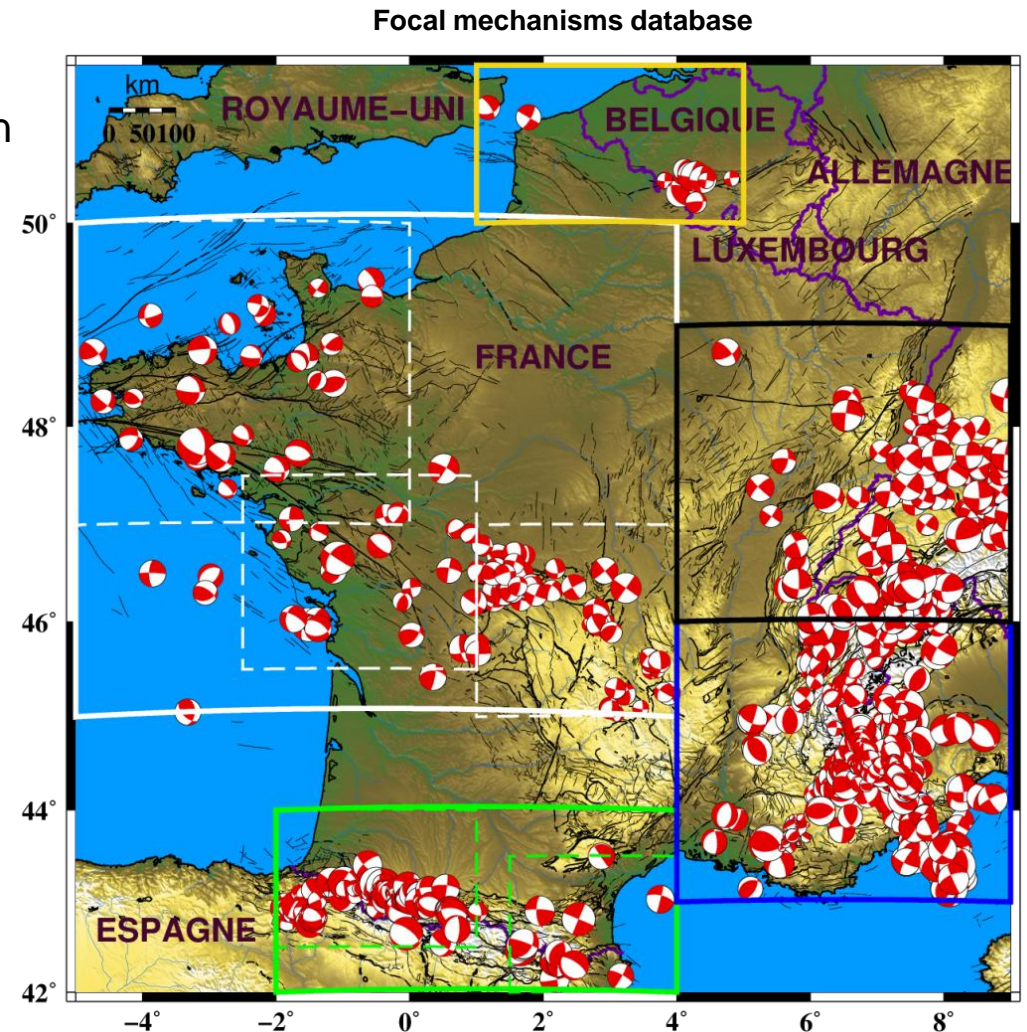

▪ In the meantime, **high disparities** remain associated to the instrumental seismicity:

- in term of average depths
- in term of focal mechanisms

➤ Is this picture traduces the structural inheritance of the crust?

➤ Can we use it as a key to understand seismicity engines:

- Regional tectonics
- Fluids impacts
- Induced and triggered seismicity
- Surface loads

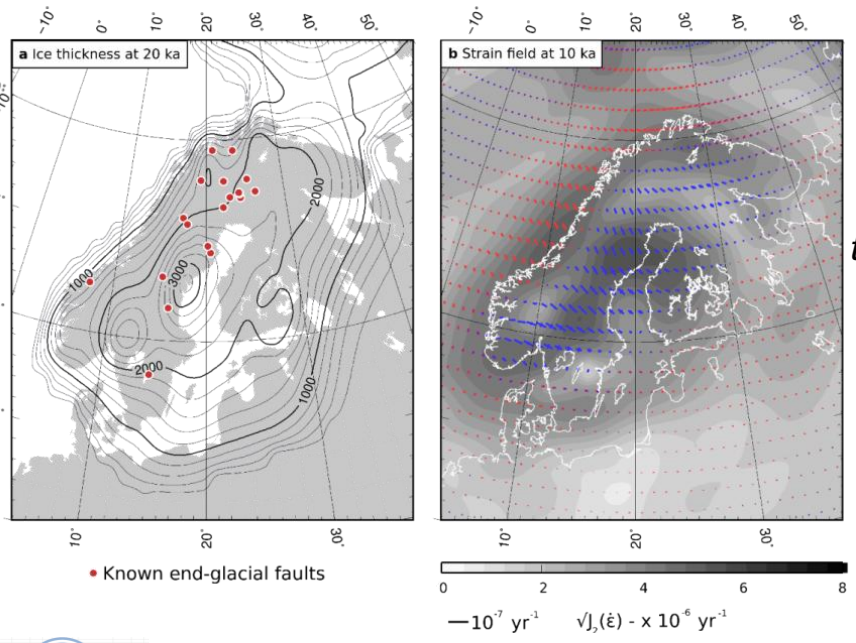

Bollinger 2017 (SINAPS@ plenary meeting)

# Available data and questions

- Crustal stress changes induced by surface masses redistribution can load existing fault systems pushing them to the point of failure, or can change the stresses preventing failure on already loaded faults.

➔ Evidence for the release of long-term tectonic strain stored in continental interiors through large intraplate earthquakes

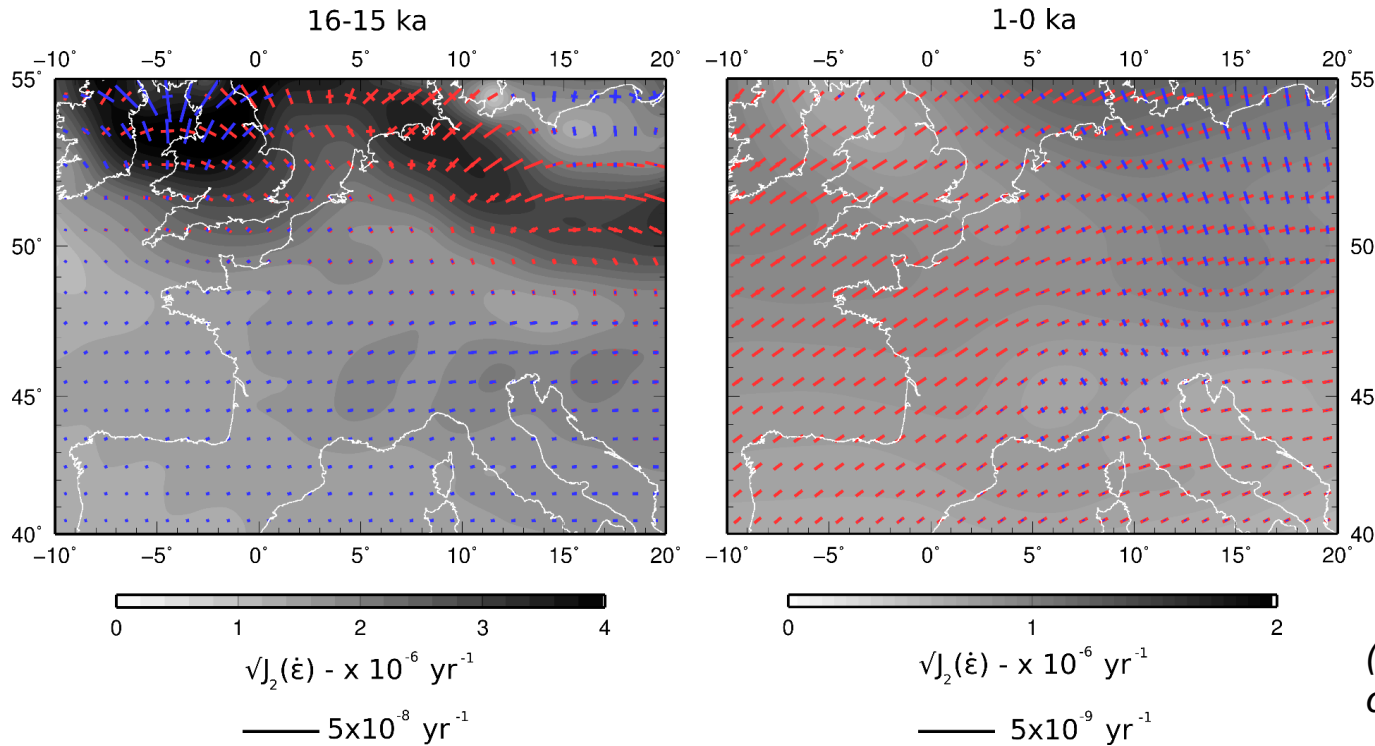

(Horizontal strain rate tensor – blue= extension; red= compression)

Stuaragurra Fault scarp (after Dehls et al., 2000)

# Available data and questions

- Despite its distance to Fennoscandia, western Europe is also affected by climatically derived strain waves during the Quaternary

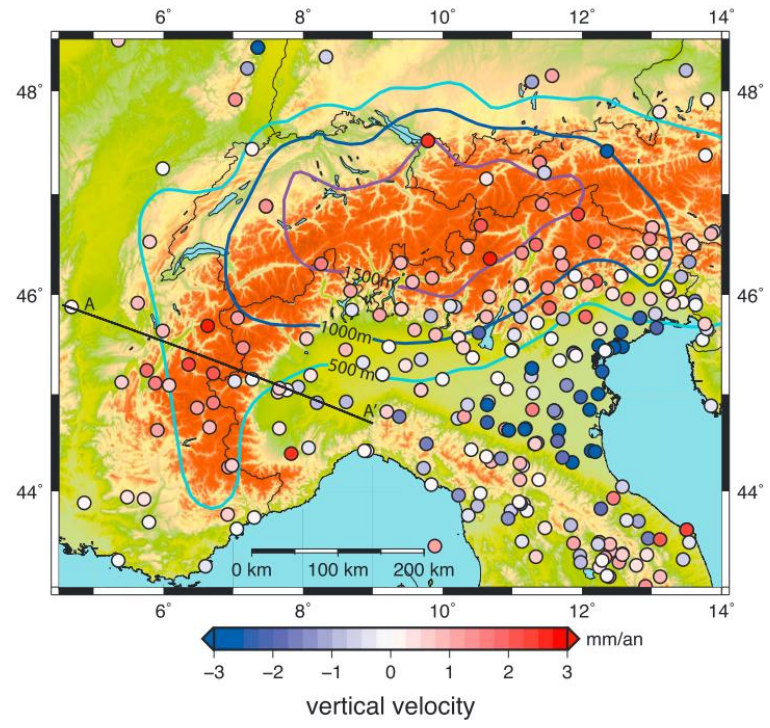

Craig et al., (2016) – SINAPS@ project

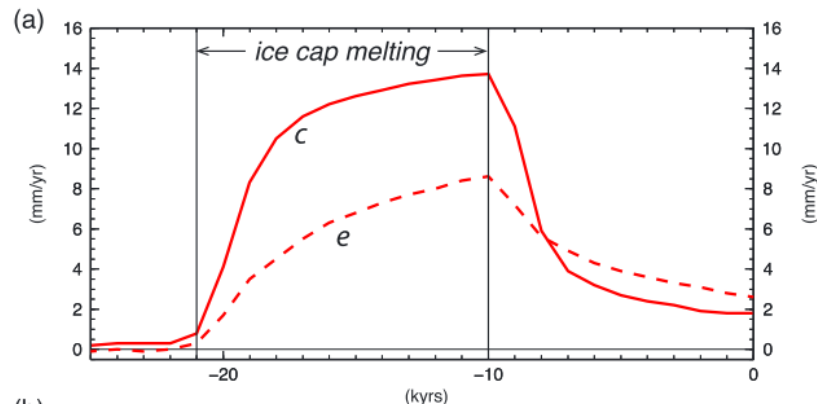

# Available data and questions (example of the French metropolitan territory)

▪ Various hypothesis [Lyon-Caen, 1989; Gudmundsson, 1994; Champagnac, 2009] proposed to explain geodetic uplift in inner Alps [Schaer and Jeanrichard, 1974; Serpelloni et al., 2013].

➔ Numerical modeling (Chéry et al., 2016) argue in favor of the post-glacial rebound as the main engine for the observed geodetic uplift (need for a weak mantle beneath the Alps).

Chéry et al., 2016

- Understanding tectonic processes in intraplate domains

## ➤ DEFORM 3D program (Geosciences Montpellier)

- Updated map of deformation rates from GPS data (France scale) + 3D numerical modeling of southern France integrating deglaciation, erosion and deep structures geometry (C. Masson, PhD);

- ***Characterization of erosion rates in Pyrenees and Cevennes regions (objective= provide constraints to erosional forcing in numerical models);***

- Development of theoretical models integrating rheological variations traducing structural inheritance + integration in numérical models forced by regional tectonic stresses (A. Tarayoun, PhD);

- ***3D numerical modeling of western Europe integrating main tectonics structures and large set of forcing. Confrontation with seismicity (Postdoc, 2018-2020)***

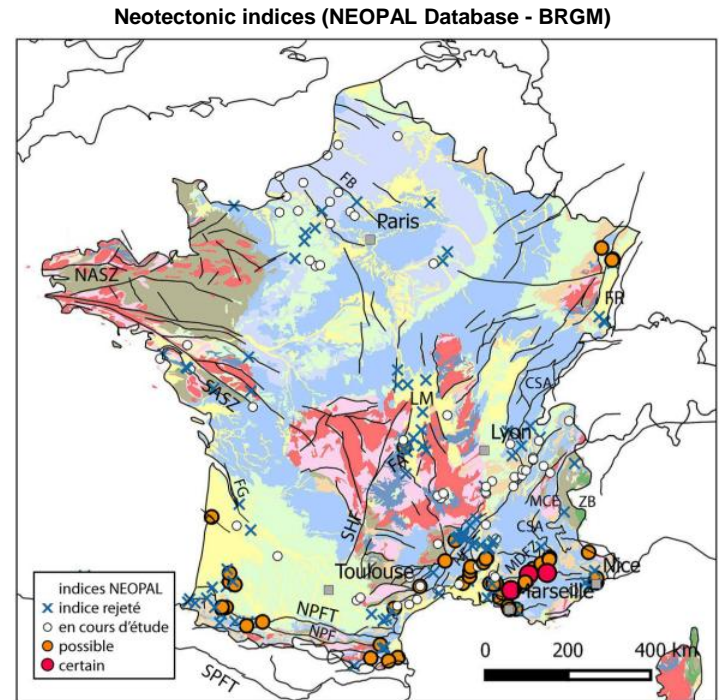

- Expand the temporal coverage of the neotectonic indices to make the difference between alternative models + lack of holocene markers (impact of climatic cycles)

➤ Have a look on dating techniques that allow resolving the timing of the tectonic and climatic events on larger time span

Method	Age range			
	10 <sup>3</sup>	10 <sup>4</sup>	10 <sup>5</sup>	10 <sup>6</sup> years
radiocarbon	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>5</sup> years]			
K-Ar, Ar-Ar	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>6</sup> years]			
U-series	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>5</sup> years]			
<sup>210</sup> Pb	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>4</sup> years]			
U-Pb, Th-Pb	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>6</sup> years]			
isotopic cosmogenic nuclides	<sup>3</sup> He	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>5</sup> years]		
	<sup>10</sup> Be	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>5</sup> years]		
	<sup>14</sup> C	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>4</sup> years]		
	<sup>21</sup> Ne	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>5</sup> years]		
	<sup>26</sup> Al	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>5</sup> years]

radiogenic	luminescence	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>5</sup> years]		
	ESR	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>5</sup> years]		
	fission-track apatite zircon	[Bar chart showing range from 10 <sup>4</sup> to 10 <sup>6</sup> years]		
sidereal	dendrochronology	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>4</sup> years]		
	varve chronology	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>4</sup> years]		
	sclerochronology	[Bar chart showing range from 10 <sup>3</sup> to 10 <sup>4</sup> years]		

Bertran et al., 2016 (SINAPS@ project)

Organizing a workshop on dating techniques to estimate/constrain age of faulting

- Faults identification and characterization

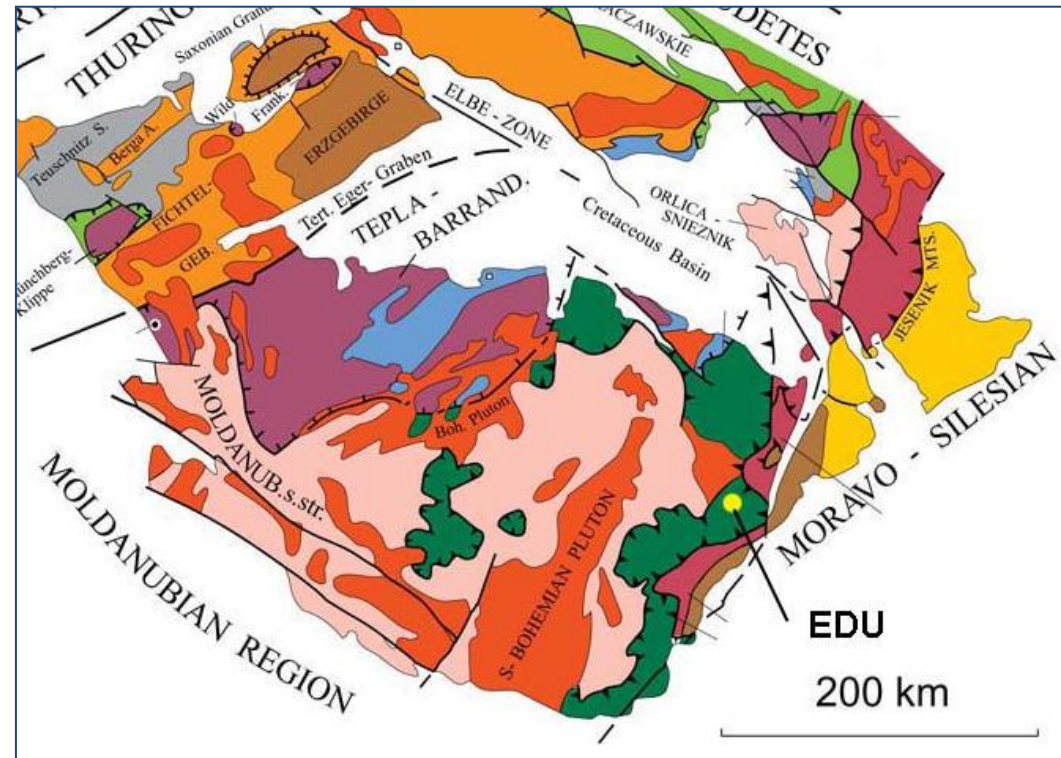

- Developing procedures for faults identification and parametrization of potentially seismogenic faults in areas with low seismicity

- Development of a database of active faults for the Bohemian Massif

- Field research (reconnaissance surveys and mapping, shallow geophysics, minor trenching, fault gouge research,...)

- Development of «Guidelines » for detecting active and potentially active seismogenic faults in areas with low seismicity and characterization of zones with diffuse seismicity

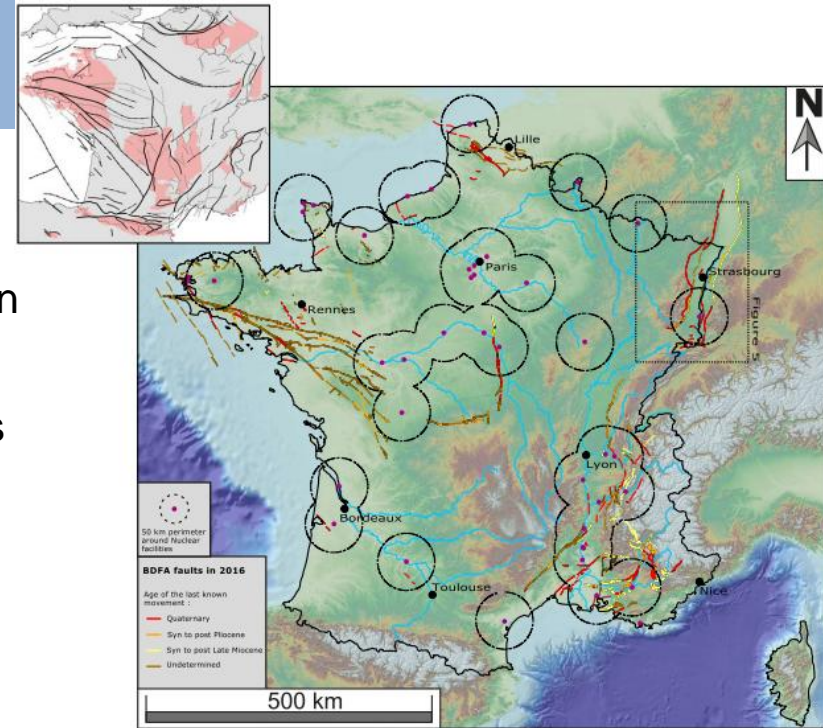

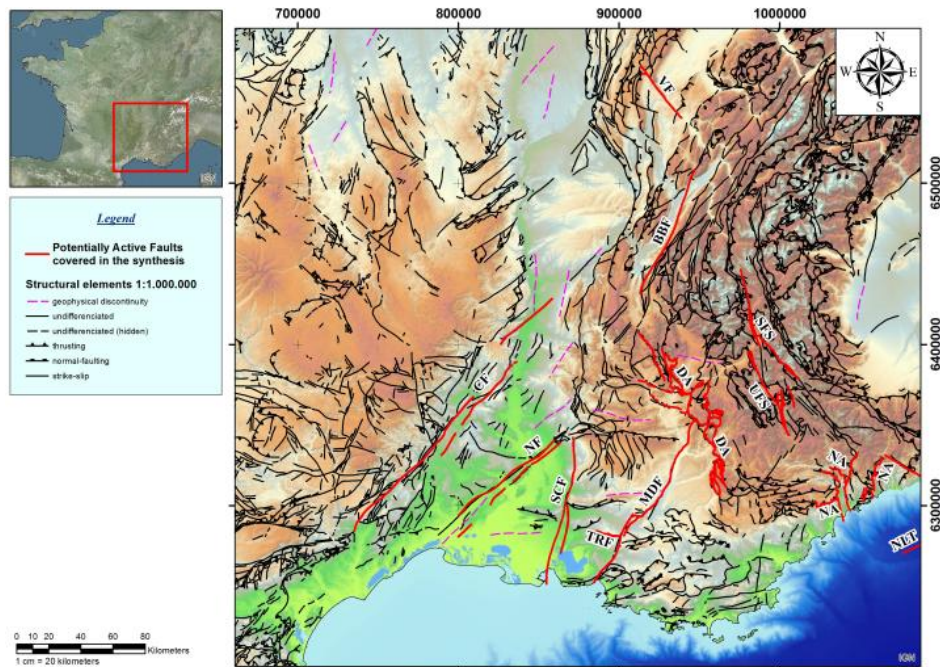

- Integration of results in PSHA

[Prachař, SIGMA2 Kick-off meeting – 06/02/2017]

# What about a french faults database ?

- Regional or localized information about faults stored in different studies/databases
- ➔ Lack of a unified database of potentially active faults at the scale of the whole french metropolitan territory

Jomard et al., 2017 - BDFA

Sengelen et al., 2014 – SIGMA project

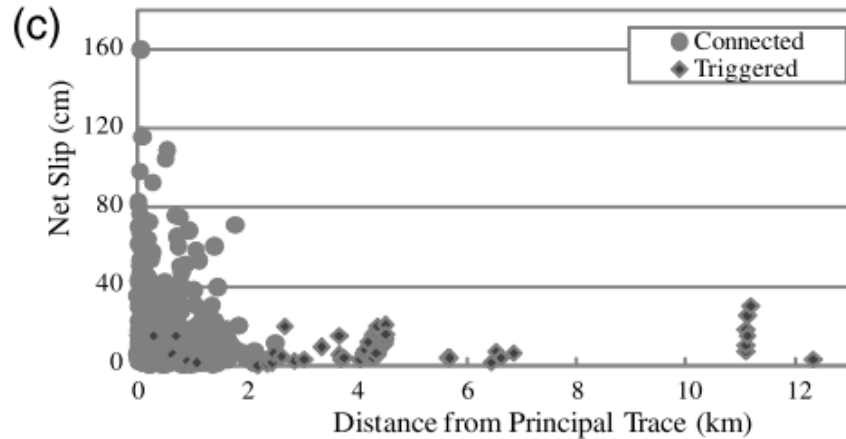

PFDHA (Probabilistic Fault Displacement Hazard Assessment) deals with evaluating potential surface fault displacement due to faulting events in a probabilistic manner.

$$\nu(d) = \alpha \int_{m_0}^{m_{max}} \int_0^{\infty} f(m) f(r|m) \underline{P(D > d|m, r)} dr dm$$

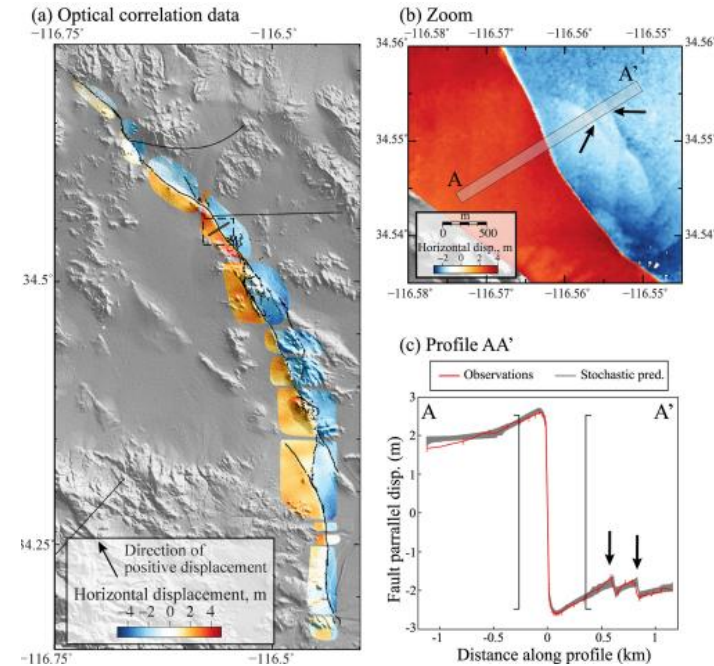

→ Slip exceedance term

- Reducing the magnitude range of application ;
- Sensitivity analysis of results according to the level of knowledge for a fault;
- Dealing accurately with secondary ruptures off main-faults

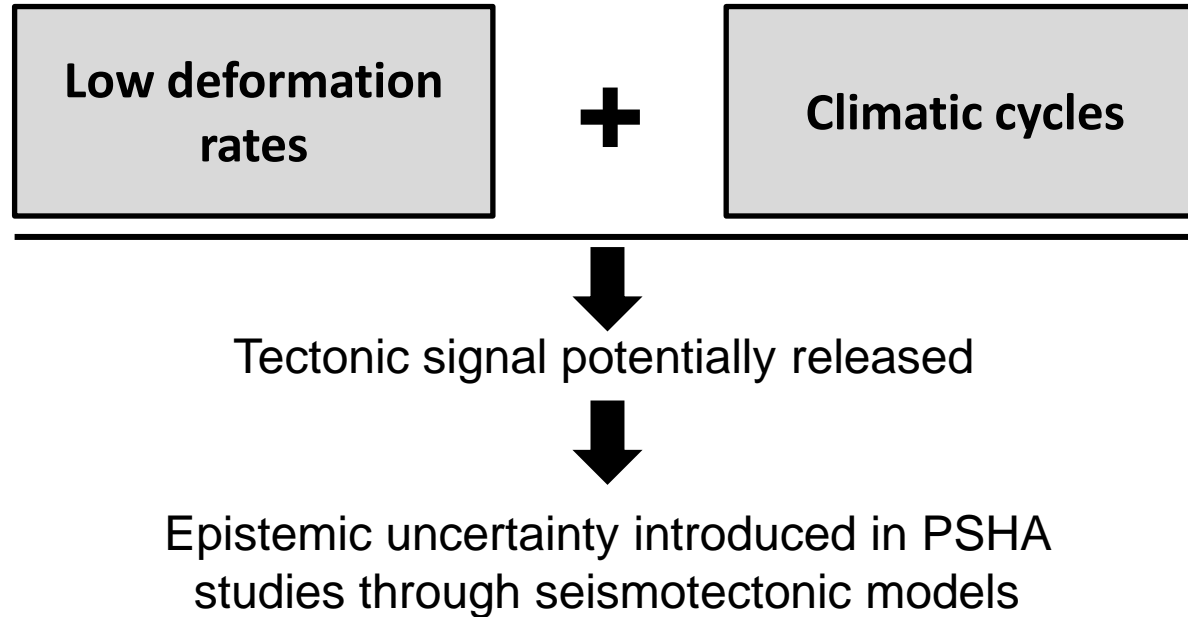

Petersen et al., 2011

Gombert et al., 2018

« Seismotectonic models: how better understanding tectonic processes and characterizing faults in intraplate domain?»

- 
- Understanding crustal deformation engines;
  - Improving tectonic and climatic episodes dating;
  - Identification and parametrization of faults at a regional scale (Bohemian Massif)
  - PFDHA approach
